## **Brief Report**

## **CRP Dryland Systems**

# Activity Cluster: (CA) 4.2.: Improving the productive use of marginal lands in mixed farming and pastoral systems

The main goal of this activity is identifying and implementing alternative land use options for a sustainable management of the marginal land resources in three countries (Uzbekistan, Kazakhstan and Turkmenistan) for improving land productivity and livelihood of farmers and agropastoral communities and providing eco-systems services

**Action Site:** Aral Sea

Region: Ylyas Farm, Karabuga village, Karauzyak district, Karakalpakstan

**Sub-activity:** "Crops Diversification in mixed farming and in rice fallows on marginal lands in Karakalpakstan"

**Year: 2014** 

**Reporting Center:** International Center for Biosaline Agriculture (ICBA) & AVRDC (The World Vegetable Center)

# **Outputs:**

Farmer-participatory evaluation and scaling up of farmer-acceptable and high-yielding varieties/improved lines of salt tolerant crops and domesticated halophytes with rapid accumulation of green biomass and achievable sugar, protein, oil content, stover and seed yields at Ylyas dekhkan farm , Karabuga village, Karauzyak district

Planting of drought and salt tolerant sorghum (3 varieties); pearl millet (2), sesame (1), fodder beet (1); maize (2) forage and vegetable legumes (6), topinambur (2) and kenaf (1) in mixed farming at rice fallows and/or in cotton field margins (salt affected, abandoned lands) on the area of 0,006 ha each

Developing of management practices (crop, soil and irrigation) for the promising drought and salt tolerant high yield crops in mixed farming system to optimize crops diversification and productivity under marginal and saline conditions.

Conducting field seminar for young farmers and women-group at Karabuga village on technology of cultivation and seed production of selected new valuable crops for their quick adoption of at householder lands

Agricultural sustainability and food security inarid and semi-arid areas of the Aral Sea Basin are limited by the salinization of arable land, and by water availability. The biological potential of some agricultural crops to withstand the salinization and water deficit may become a key component of farming systems. Several crops were selected for this study to investigate their performance under saline water and soil conditions in the Karakalpakistan Republic. Growth performance and yield

productivity were analyzed in the downstream arid zone of the Aral Sea Basinat two soil salinity levels, calculated as total dissolved salts (TDS): low saline (< 0.9 g/l), and medium saline (> 1.5 g/l).

Ground water salinity variedbetween3g/l and 9g/l from spring to summer, and irrigation water salinity varied between1.6g/l and 3.1g/l,with sulphate as the predominant anion and sodium as the predominant cations in both ground and irrigation water.

The results showed insignificant differences between crop varieties in seed germination rate, plant height, and accumulation of green biomass, when cultivated on soils with light clay texture and low level of soil salinity (Table 1). A sharp decrease (by about 2.6 times) in plant density and survival rate is seen for maize grown on medium saline soil with heavy texture

Table 1. Agrobiological characteristics and yield of green forage and grain production for

Variety/Improved lines	Field seed germination rate (%)	Height of plant (cm)	Period of vegetation (days)	Yield of green forage (t/ha-1)	Grain yield (t/ha-1)					
Pearl millet										
Hashaki1	90±1.3	182.5±1.5	81.5	34.9±5.8	2,0

llkhom	14.9	5.0	3.4	20.7	2.2	43.9	92

Chemical composition of vegetable mung bean green seeds (Uzbekistan)

Variety	Common sugar,%	Fat,%	Starch,%	Protein, %	Cellulose, %	Nitrates, mg/kg
Kakhrabo	4,2	0,98	2,0	18,7	4,1	88
Durdona	4,0	1,90	1,8	18,8	5,9	80
Turron	4,8	0,96	1,9	18,9	4,0	84

# **Outcomes:**

Salt affected margins taken under cultivation of low inputs salt tolerant crops

Crops design (Ylias farmer in the center) Karabuga, Karakalpakstan

Experimental trials during plants establishment (seed germination –a most sensitive stage)

The same trials after 3 months

Drs Zulfia Sultaniva and Ganiboy Khodjabergenov responsable for filed data monitoring

Sorghum ISCV 93046 ICBA improved line (for seeds) under fish net against birds

Kenaf ((Hibiscus cannabinus ) – fast growing salt and drought tolerant (at the abandoned cotton filed margins)

Mung bean Durdona variety, AVRDC germplasm

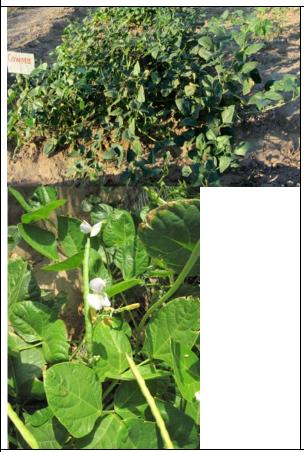

Mung bean Marjon variety (local adapted )

Yard long bean (Oltin Soch variety) –AVRDC germplasm

Cow pea (ICBA improved line) salt tolerant (covering vegetable legume)

#### **Outcomes:**

- 1. Average threshold salinity level for examined crops ranged from 1,7-8.5 dS/m<sup>-1</sup>; the most sensitive to soils salinity in the field were shown for corn, some of legumes followed by sunflower, sesame, sorghum, fodder beet. Sorghum improved lines ISCV 93046, SPV 1441, pearl millet, kenaf, artichoke, improved lines of caw pea showed a significant increasing in green and dry biomass.
- 2. Seed germination and early stages of green biomass accumulation are the most sensitive to soils salinity for all investigated crops
- 3. 18 low –input dual-purpose crops (sorghum, pearl millet, vegetable legumes, early maturity drought tolerant corn, fodder beet, vegetable legumes, sesame, kenaf and artichoke) were identified for the reclamation of salt affected lands at Karabuga farm
- 4. Majority of early maturity sorghum, pearl millet and legumes are salt tolerant and drought tolerant (with high water use efficiency capacity). Being cultivated on saline soils with shallow water table requires only two limited irrigation during vegetation season
